## ACKNOWLEDGEMENT

We express our heartfelt thanks to our honorable **Vice Chancellor Dr. C. MUTHAMIZHCHELVAN**, for being the beacon in all our endeavors.

We would like to express my warmth of gratitude to our **Registrar Dr. S. Ponnusamy**, for his encouragement

We express our profound gratitude to our **Dean (College of Engineering and Technology) Dr. T. V.Gopal**, for bringing out novelty in all executions.

We would like to express my heartfelt thanks to Chairperson, School of Computing **Dr. Revathi Venkataraman**, for imparting confidence to complete my course project

We wish to express my sincere thanks to **Course Audit Professor Dr. Annapurani Panaiyappan, Professor and Head, Department of Networking and Communications and Course Coordinators** for their constant encouragement and support.

We are highly thankful to our my Course project Faculty **J PRABAKARAN , ASSISTANT PROFESSOR, NWC**, for his/her assistance, timely suggestion and guidance throughout the duration of this course project.

Finally, we thank our parents and friends near and dear ones who directly and indirectly contributed to the successful completion of our project. Above all, I thank the almighty for showering his blessings on me to complete my Course project.

## 1. INTRODUCTION

Access control lists are used for controlling permissions to a computer system or computer network. They are used to filter traffic in and out of a specific device. Those devices can be network devices that act as network gateways or endpoint devices that users access directly.

On a computer system, certain users have different levels of privilege, depending on their role. For example, a user logged in as network administrator may have read, write and edit permissions for a sensitive file or other resource. By contrast, a user logged in as a guest may only have read permissions.

Access control lists can help organize traffic to improve network efficiency and to give network administrators granular control over users on their computer systems and networks. ACLs can also be used to improve network security by keeping out malicious traffic.

### **ABSTRACT:**

An access control list (ACL) is a list of rules that specifies which users or systems are granted or denied access to a particular object or system resource. Access control lists are also installed in routers or switches, where they act as filters, managing which traffic can access the network.

Each system resource has a security attribute that identifies its access control list. The list includes an entry for every user who can access the system. The most common privileges for a file system ACL include the ability to read a file or all the files in a directory, to write to the file or files, and to execute the file if it is an executable file or program. ACLs are also built into network interfaces and operating systems (OSes), including Linux and Windows.

# REQUIREMENTS

## 1.1 Requirement Analysis

From the given scenario, we draw the following requirements:

1. Identifying the appropriate hardware which would be used (Cisco Packet Tracer)
2. Users on the internet should be able to access only https on the WEB server.
3. Users on the internet should have access only to the public IP address of the server and not the private IP address.
4. The users in the organization should have full access to the server.
5. TCP/IP Network design with IP addressing
6. Features and configuration required on the hardware with explanation

We need to configure a network design keeping the following requirements in mind.

## 1.2 Hardware Requirement

From the given scenario, we draw the following requirements:

For UNIVERSITY SRM (Private Network):

Hardware Required:

3x Server – PT Primary Server

2x Router (For address)

2x Switches:

1x STUDENT SIDE Switch

1x ADMIN SIDE Switch

7x End Devices:

3x PCs for STUDENT

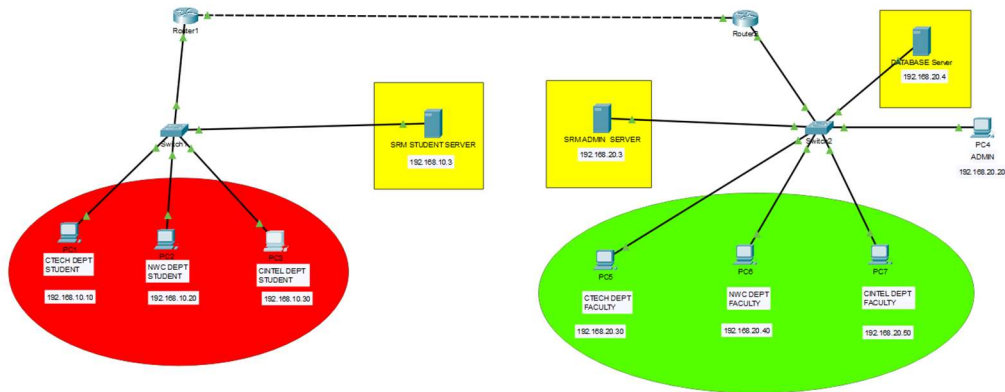

1x PCs for ADMIN

3x PCs for FACULTY

## 2. ARCHITECTURE AND DESIGN

### 2.1 Network Architecture

The network architecture is as follows:

The architecture consists of three major networks:

- UNIVERSITY Network(s)
- PRIVATE Internet
- Network maintained by the Internet Service Provider

These networks are interconnected with each other with varying degrees (discussed in the implementation chapter).

### 3. IMPLEMENTATION

#### 3.1 Address Table

The address table is as follows:

Device	Interface	Address
STUDENT Server	Fa0	192.168.10.3
ADMIN Server	Fa0	192.168.20.3
Data base Server	Fa0	192.168.20.4
Students PC	Fa0/0	192.168.10.10 to 192.168.10.30
Faculty PC	Fa0	192.168.20.30
	Fa0/0	192.168.20.50
	Fa0/0	192.168.20.40
Admin PC	Fa0/0	192.168.20.20

The university Router has NAT configured with an ACL.

The Access Control List contains the entire broadband network. Any request from that network is translated to the private IP of the server.

Static Routing is used on all the routers to interconnect the networks.

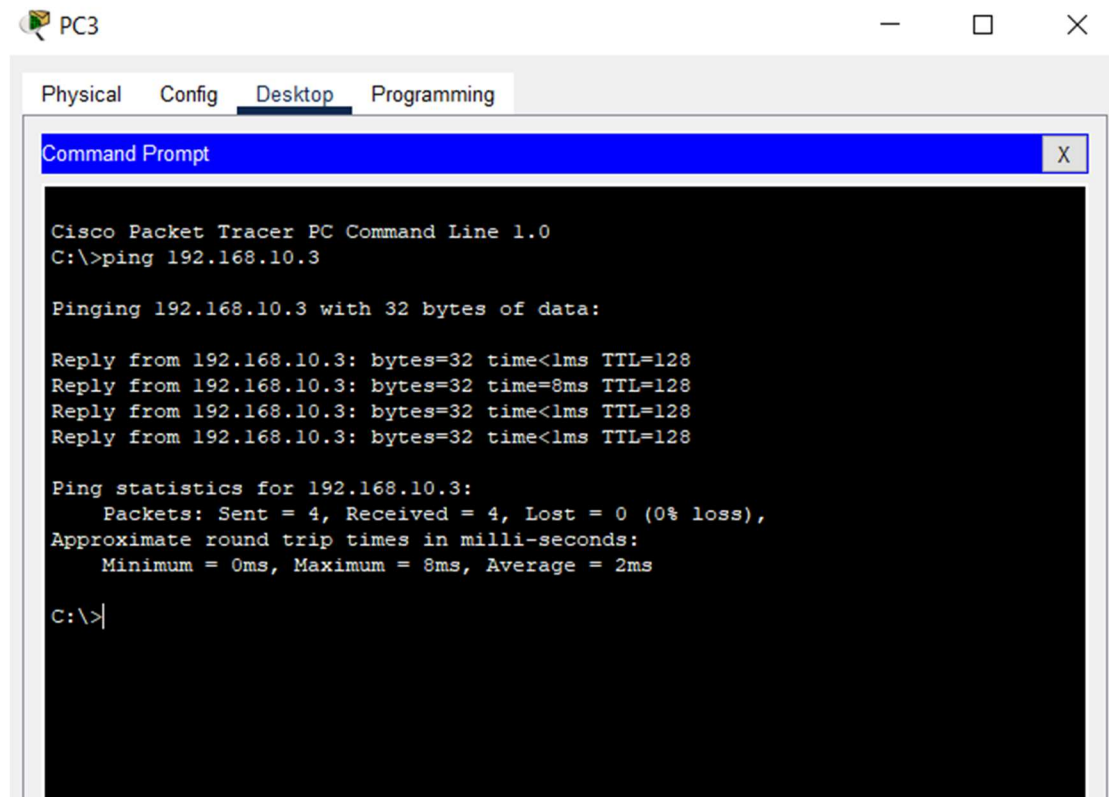

## 4. RESULTS AND DISCUSSION

### 4.1 Connection Check

The network connections were checked by ping requests:

STUDENTS PC:

The screenshot shows a window titled "PC3" with tabs for "Physical", "Config", "Desktop", and "Programming". The "Desktop" tab is active, displaying a "Command Prompt" window. The command prompt shows the execution of a ping command to 192.168.10.3, resulting in four successful replies with 32 bytes of data, a time of 8ms, and a TTL of 128. The ping statistics indicate 4 packets sent, 4 received, and 0% loss, with an average round trip time of 2ms.

```
Cisco Packet Tracer PC Command Line 1.0
C:\>ping 192.168.10.3

Pinging 192.168.10.3 with 32 bytes of data:

Reply from 192.168.10.3: bytes=32 time<1ms TTL=128
Reply from 192.168.10.3: bytes=32 time=8ms TTL=128
Reply from 192.168.10.3: bytes=32 time<1ms TTL=128
Reply from 192.168.10.3: bytes=32 time<1ms TTL=128

Ping statistics for 192.168.10.3:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 8ms, Average = 2ms

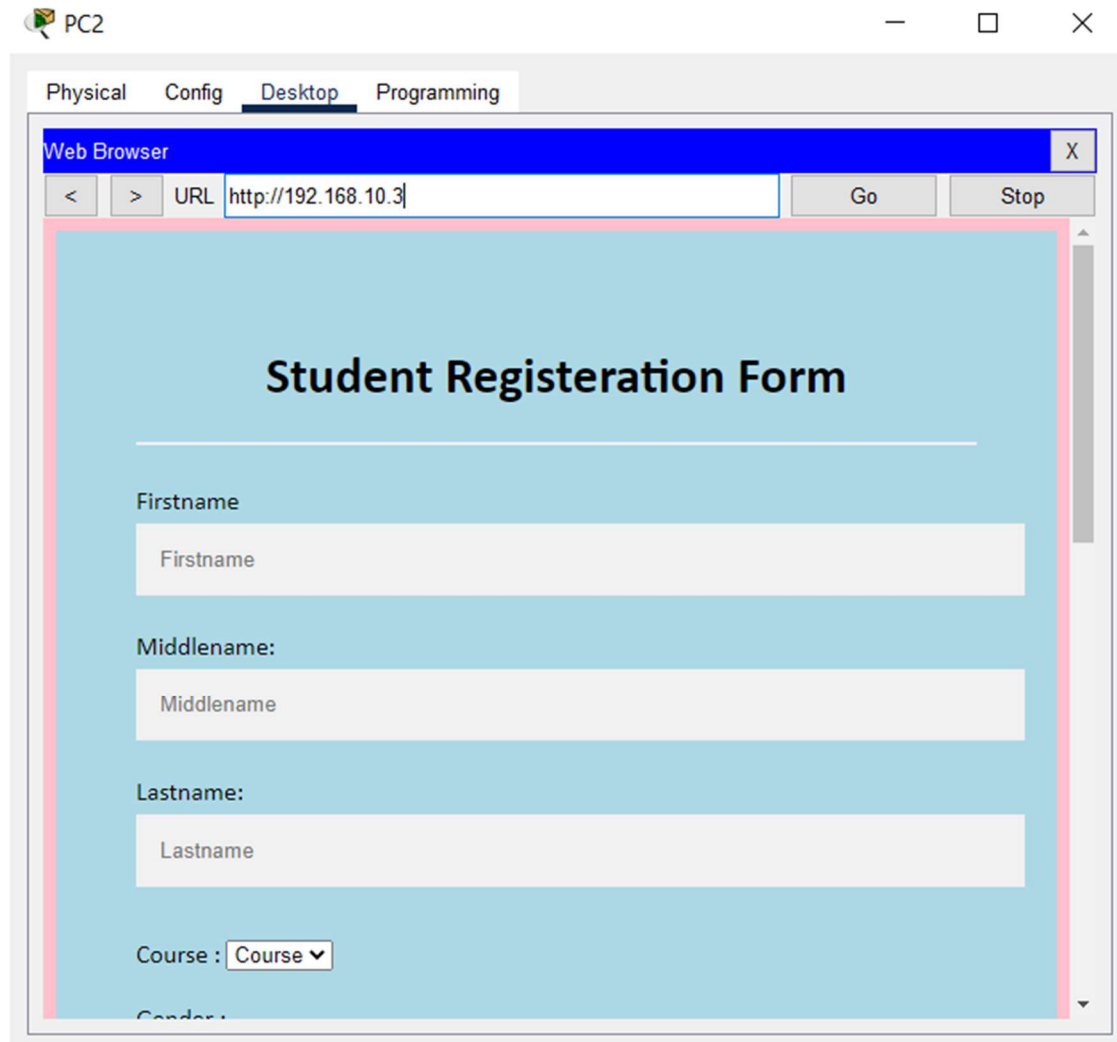

C:\>|
```

## ADMIN PC

## 4.2 HTTPS Check

The server access was checked with HTTPS by using a browser:

PC5

router(config)#access-list 10 deny 192.168.20.50 0.0.0.255
```

## **ASYMMETRIC AND SYMMETRIC ALGORITHMS**

Asymmetric cryptography, also known as public-key cryptography, is a process that uses a pair of related keys -- one public key and one private key -- to encrypt and decrypt a message and protect it from unauthorized access or use.

A public key is a cryptographic key that can be used by any person to encrypt a message so that it can only be decrypted by the intended recipient with their private key. A private key -- also known as a secret key -- is shared only with key's initiator.

When someone wants to send an encrypted message, they can pull the intended recipient's public key from a public directory and use it to encrypt the message before sending it. The recipient of the message can then decrypt the message using their related private key.

If the sender encrypts the message using their private key, the message can be decrypted only using that sender's public key, thus authenticating the sender. These encryption and decryption processes happen automatically; users do not need to physically lock and unlock the message.

Many protocols rely on asymmetric cryptography, including the transport layer security (TLS) and secure sockets layer (SSL) protocols, which make HTTPS possible.

The encryption process is also used in software programs that need to establish a secure connection over an insecure network, such as browsers over the internet, or that need to validate a digital signature.

Increased data security is the primary benefit of asymmetric cryptography. It is the most secure encryption process because users are never required to reveal or share their private keys, thus decreasing the chances of a cybercriminal discovering a user's private key during transmission.

[Symmetric encryption](#) is a type of encryption where only one key (a secret key) is used to both encrypt and decrypt electronic data. The entities communicating via symmetric encryption must exchange the key so that it can be used in the decryption process. This encryption method differs from asymmetric encryption where a pair of keys - one public and one private - is used to encrypt and decrypt messages.

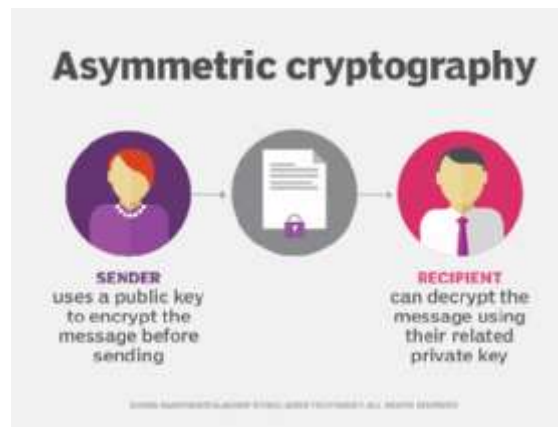

By using symmetric encryption algorithms, data is "scrambled" so that it can't be understood by anyone who does not possess the secret key to decrypt it. Once the intended recipient who possesses the key has the message, the algorithm reverses its action so that the message is returned to its original readable form. The secret key that the sender and recipient both use could be a specific password/code or it can be random string of letters or numbers that have been generated by a secure random number generator (RNG). For banking-grade encryption, the symmetric keys must be created using an [RNG](#) that is certified according to industry standards, such as [FIPS 140-2](#).

**Aim: To perform asymmetric and symmetric cryptographic algorithms**

**Procedure (for Asymmetric):**

- Asymmetric encryption uses a mathematically related pair of keys for encryption and decryption: a public key and a private key. If the public key is used for encryption, then the related private key is used for decryption. If the private key is used for encryption, then the related public key is used for decryption.

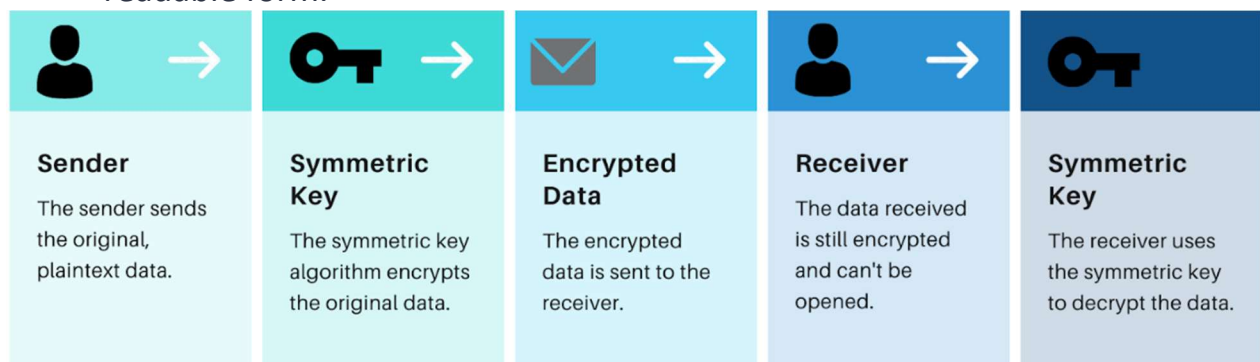

- The two participants in the asymmetric encryption workflow are the sender and the receiver.
- Each has its own pair of public and private keys.
- First, the sender obtains the receiver's public key. Next, the plaintext message is encrypted by the sender using the receiver's public key. This creates ciphertext.
- The ciphertext is sent to the receiver, who decrypts it with their private key, returning it to legible plaintext.

### (Symmetric):

- In symmetric encryption, the key that encrypts a message or file is the same key that can decrypt them.
- The sender of the data uses the symmetric key algorithm to encrypt the original data and turn it into cipher text.
- The encrypted message is then sent to the receiver who uses the same symmetric key to decrypt or open the cipher text or turn it back into readable form.

### Sample Case for asymmetric encryption by using RSA:

Let us take an example of this procedure to learn the concepts. For ease of reading, it can write the example values along with the algorithm steps.

- Choose two large prime numbers P and Q

Let  $P = 47$ ,  $Q = 17$

- Calculate  $N = P \times Q$

We have,  $N = 7 \times 17 = 119$ .

- Choose the public key (i.e., the encryption key)  $E$  such that it is not an element of  $(P-1) \times (Q-1)$

1. Let us find  $(7-1) \times (17-1) = 6 \times 16 = 96$

2. The factors of 96 are 2, 2, 2, 2, 2, and 3 (because  $96 = 2 \times 2 \times 2 \times 2 \times 2 \times 3$ ).

3. Therefore, it can select  $E$  such that none of the factors of  $E$  is 2 and 3. We cannot choose  $E$  as 4 (because it has 2 as a factor), 15 (because it has 3 as a factor) and 6 (because it has 2 and 3 both as factors).

4. Let us choose  $E$  as 5 (it can have been any other number that does not its factors as 2 and 3).

- Choose the private key (i.e., the decryption key)  $D$  including the following equation is true:

$$(D \times E) \bmod (P-1) \times (Q-1) = 1$$

1. Let us substitute the values of  $E$ ,  $P$ , and  $Q$  in the equation.

2. We have  $(D \times 5) \bmod (7-1) \times (17-1) = 1$ .

3. That is,  $(D \times 5) \bmod (6) \times (16) = 1$ .

4. That is,  $(D \times 5) \bmod (96) = 1$

5. After some calculations, let us take  $D = 77$ . Then the following is true:  $(77 \times 5) \bmod (96) = 385 \bmod 96 = 1$  which is what we wanted.

- For encryption, calculate the cipher text (CT) from the plain text (PT) as follows:

$$CT = PT^E \bmod N$$

Let us assume that we want to encrypt plain text 10. Then, we have

$$CT = 10^5 \bmod 119 = 100000 \bmod 119 = 40.$$

- Send CT as the cipher text to the receiver.

Send 40 as the cipher text to the receiver.

- For decryption, calculate the plain text (PT) from the cipher text (CT) as follows:

$$PT = CT^D \bmod N$$

It perform the following:

$$PT = 40^{77} \bmod 119$$

That is,

$$PT = 40^{77} \bmod 119 = 10, \text{ which was the original plaintext of step5.}$$

### **Sample case for symmetric encryption by using AES:**

- Rounds  $N_r = 6 + \max\{N_b, N_k\}$   $N_b$ = 32-bit words in the block  $N_k$ = 32-bit words in key

1. Substitute Bytes: Each byte is replaced by byte indexed by row (left 4-bits) & column (right 4-bits) of a 16x16 table
  2. Shift Rows: 1st row is unchanged. 2nd row does 1 byte circular shift to left 3rd row does 2 byte circular shift to left .4th row does 3 byte circular shift to left.
  3. Mix Columns: Effectively a matrix multiplication in GF(28) using prime polynomial  $m(x) = x^8 + x^4 + x^3 + x + 1$
- Uses arithmetic in the finite field GF(28) with irreducible polynomial  $m(x) = x^8 + x^4 + x^3 + x + 1$  which is (100011011) or {11B} Example:  $\{02\} \bullet \{87\} \bmod \{11B\} = (1\ 0000\ 1110) \bmod \{11B\} = (1\ 0000\ 1110) \boxtimes (1\ 0001\ 1011) = (0001\ 0101)$
  - XOR state with 128-bits of the round key
  - Use four byte words called  $w_i$ . Subkey = 4 words. For AES-128: First subkey  $(w_3, w_2, w_1, w_0) = \text{cipher key}$  Other words are calculated as follows:  $w_i = w_{i-1} \boxtimes w_{i-4}$  1. for all values of  $i$  that are not multiples of 4. For the words with indices that are a multiple of 4 ( $w_{4k}$ ): RotWord: Bytes of  $w_{4k-1}$  are rotated left shift (nonlinearity) 2. 3. SubWord: SubBytes fn is applied to all four bytes. (Diffusion) The result  $rsk$  is XOR'ed with  $w_{4k-4}$  and a round constant  $rcon$  (breaks Symmetry):  $w_{4k} = rsk \boxtimes w_{4k-4} \boxtimes rcon$  For AES-192 and AES-256, the key expansion is more complex.

## AES Example Key Expansion

- AES decryption is not identical to encryption .But each step has an inverse.

Asymmetric cryptography is typically used to authenticate data using digital signatures. A digital signature is a mathematical technique used to validate the

authenticity and integrity of a message, software or digital document. It is the digital equivalent of a handwritten signature or stamped seal.

Based on asymmetric cryptography, digital signatures can provide assurances of evidence to the origin, identity and status of an electronic document, transaction or message, as well as acknowledge informed consent by the signer.

**Asymmetric cryptography can also be applied to systems in which many users may need to encrypt and decrypt messages, including:**

- **Encrypted email.** A public key can be used to encrypt a message and a private key can be used to decrypt it.
- **SSL/TLS.** Establishing encrypted links between websites and browsers also makes use of asymmetric encryption.
- **Cryptocurrencies.** [Bitcoin](#) and other cryptocurrencies [rely on asymmetric cryptography](#). Users have public keys that everyone can see and private keys that are kept secret. Bitcoin uses a cryptographic algorithm to ensure only legitimate owners can spend the funds.

### **Uses of symmetric key algorithm:**

Banking Sector. Due to the better performance and faster speed of symmetric encryption, symmetric cryptography is typically used for bulk encryption of large amounts of data. Applications of symmetric encryption in the banking sector include:

- Payment applications, such as card transactions where PII (Personal Identifying Information) needs to be protected to prevent identity theft or fraudulent charges without huge costs of resources. This helps lower the risk involved in dealing with payment transactions on a daily basis.
- Validations to confirm that the sender of a message is who he claims to be.
- Data at rest. Data at rest is data that is not actively moving from device to device or network-to-network such as data stored on a hard drive, laptop, flash drive, or archived/stored in some other way. Data protection at rest aims to secure inactive data stored on any device or network. While data at rest is sometimes considered to be less vulnerable than data in transit, attackers often find data at rest a more valuable target than data in motion. For protecting data at rest, enterprises can simply encrypt sensitive files prior to storing them and/or choose to encrypt the storage drive itself.
- The best way to encrypt data at rest is by whole disk or full disk encryption. Full disk encryption has several benefits compared to regular file or folder

encryption, or encrypted vaults. Nearly everything including the swap space and the temporary files is encrypted. Encrypting these files is important, as they can reveal important confidential data. With a software implementation, the bootstrapping code cannot be encrypted, however. For example, BitLocker Drive Encryption leaves an unencrypted volume to boot from, while the volume containing the operating system is fully encrypted. In addition, the decision of which individual files to encrypt is not left up to users' discretion. This is important for situations in which users might not want or might forget to encrypt sensitive files.

## **CONCLUSION:**

Hence the implementation of Access Control List and Asymmetric and Symmetric algorithms have been successfully implemented.
